1 Introduction

This document provides an overview of the methodology used for MPE (averaged power density) RF exposure compliance of the 5G mmWave radios on next generation iPhone.

Due to the presence of multiple antenna arrays, and multiple antenna beams for each antenna array, we propose to use a combination of simulation and measurement to demonstrate MPE (sPD) compliance. At a high level, the discussion is grouped into the following topics:

- Brief introduction to MPE simulation methodologies
- Explanation of the approach to demonstrate MPE (sPD) compliance in a device with measurement to validate simulation
- Brief review of the device configuration and operation, and detailed description of the simulation methodology and results

A few things to be noted are

1. The simulation and validation methods described herein follow QC guidance for SAR Char and PD Char for determining the worst-case beam for static transmission measurements.
2. The PD simulation models are built with different CAD models for different programs.
3. Based on guidance, we intend to characterize the three highest MPE beams per polarization per module to choose the scaling factor for all other beams on that module/polarization.

2 MPE Simulation Methodology

3D full-wave simulation is used to evaluate MPE for each antenna array module's beam. Each beam is created by invoking a pre-defined codebook that has the proper array elements' excitation (i.e., magnitude and phase) to create the beam.

The following steps are taken to verify the validity of the model used for MPE simulations and then the verified model is used for the MPE calculations:

1) EM Simulation:

- Import a CAD model that represents the actual product in the simulation tool
- Define material properties inside the product based on vendor's inputs
- Perform mesh seeding and solve

2) Compile Fields and Codebook:

- Extract field data from solved model and arrange in format required by Qualcomm Module Group (MG) Script [1]
- Input PD char codebook generated by Qualcomm Webchar tool

3) MPE Calculations:

- Set averaging area to 4cm² using MG Script configuration xml file
- Run MG script to generate MPE and power limit tables for each beam ID in codebook

4) Validate Simulation Model:

- Measure MPE

- Compare measurement vs simulation
- Once a correlation is established, and model's accuracy is verified, this model will be used for computational MPE assessments

5) Run Additional Verifications:

- Use verification data generated by MG Script
- Measure MPE for worst case beams given by MG Script
- Use EM tools, MG Script to complete additional verifications

Figure 1. Model validation workflow for MPE simulation and evaluation.

3 MPE Measurements

A mmWave DAE SN 1411 module from SPEAG is used to measure the MPE (sPD) above the DUT. Figure 2 shows the setup of measurement. The mmWave E-field probe is used to measure the electric field above DUT. The near-field magnetic field and MPE are further obtained using this setup. The measurement algorithm can be found in [2] in detail.

Figure 2. MPE measurement setup.

The distance from probe sensor tip to the edge of the housing is 1.5 mm, and there is 0.5 mm gap between probe tip and the DUT surface to prevent mechanical damage. Therefore, the closest distance that the setup can measure is 2 mm as shown below in Figure 3.

Figure 3. Sketch of the probe showing that the minimum measurable distance is 2 mm.

4 MPE (sPD) Simulations

In 5G, MIMO antennas are designed to orient the beam to specific directions to improve link budgets. Most MIMOs can be configured by using the codebook with each code resulting in a different exposure. The number of codes in the codebook can be very large and measurements of all possible configurations have been shown to be impractical. Therefore, simulation is used to determine the modes/configurations that result in the highest MPE.

All elements are dual polarized patch antennas with horizontal and vertical feeds.

Simulation Models

Figure 4 is a schematic of the simulation model. There are three antenna arrays in the phone, which are back-firing array 1, back-firing array 2 and side-firing array.

Figure 4. Schematic of the simulation mode, which consists of three 5G antenna arrays, (a) back-firing array 1 (rear view), (b) back-firing array 2 (rear view), and (c) side-firing array (side view).

The measurements and simulations are correlated across different evaluating surfaces 2 mm away from each DUT surface (drawn not to scale), as shown in Figure 5 below. Six surfaces will be evaluated, respectively: front (S1), back (S2), left (S3), right (S4), top (S5) and bottom (S6). As Table 1 shows, for the three antenna arrays, only the evaluating planes within 2.5 cm from the edges of the antenna modules will be considered. This does not apply to the back-to-front or front-to-back condition since fields from the back module will be blocked at the front evaluating plane (and vice versa) by the metal parts (such as battery, MLB) in between.

The “left” and “right” edges in the report are defined relative to the front of the device.

Figure 5. Evaluating surfaces for MPE (sPD).

Table 1- PD Evaluation Planes

	Front (S1)	Rear (S2)	Left from Front View (S3)	Right from Front View (S4)	Top (S5)	Bottom (S6)
Side Array	Yes (0.4 cm)	Yes (0.4 cm)	No (7 cm)	Yes (0 cm)	No (8 cm)	No (4 cm)
Back Array 1	No (0.6 cm)	Yes (0 cm)	Yes (0.9 cm)	No (4 cm)	No (2.7 cm)	No (12 cm)
Back Array 2	No (0.6 cm)	Yes (0 cm)	Yes (0.9 cm)	No (4 cm)	Yes (0.8 cm)	No (12 cm)

MPE (sPD) Definition

After solving the 3D full-wave electromagnetic simulation, various physical quantities can be derived. To calculate PD evaluation, two physical quantities, an electric field $\vec{E}$ and a magnetic field $\vec{H}$ are needed. The actual consumption power can be expressed as the real term of the Poynting vector $\vec{S}$ from the cross product of $\vec{E}$ and complex conjugation of $\vec{H}$ as shown below:

$$\vec{S} = \frac{1}{2} \text{Re}(\vec{E} \times \vec{H}^*)$$

$\vec{S}$ can be expressed as localized power density based on a peak value of each spatial point on mesh grid. From the localized power density $\vec{S}$, the spatial-averaged power density (PD) on an evaluated area (A) can be shown as below

$$PD = \frac{1}{A} \int_A \vec{S} \cdot d\vec{A} = \frac{1}{2A} \int_A \text{Re}(\vec{E} \times \vec{H}^*) \cdot d\vec{A}$$

For the purposes of these simulations, PD is the total power density value considering the contributions of x, y, and z components of localized power density $\vec{S}$. The evaluated area A is 4 cm². To capture worst-case power density conditions, simulations and measurements were performed assuming a 100% duty cycle.

Simulation Methodology:

A time domain 3D Full-Wave Electromagnetic Simulation is performed using CST Studio Suite. The solver calculates electric and magnetic fields at discrete locations and time samples. To achieve high accuracy at all locations, the total electromagnetic energy inside the calculation domain is used as a convergence criterion. The solvers terminate when the normalized energy is decayed to -40 dB ensuring high accuracy of simulation output.

Boundary Conditions:

The boundary condition for simulating electromagnetic behavior in CST is to allow the electromagnetic waves to be electrically open at the boundary and radiated far away without reflection. CST can support the absorption boundary condition (ABC) for radiation boundary and normally requires a quarter-wavelength separation from the structure.

Source Excitation and Example Codebook:

Figure 66 shows an example of the codebook for the antenna modules. The first column of the codebook is the beam ID. “Amplitude” and “Phase” are the excitation amplitude and phase for each antenna element. Each beam has a “Paired_With” beam for concurrent MIMO streams. The last column is the index of the beam which is paired with the index shown in the second column. The “Amplitude” is in dBm, and “Phase” is in degrees. In real applications, amplitude of the input power for n258, n261 and n260 is 6 dBm.

Band	Beam_ID	Module	Ant_Group	Subarray	Ant_Type	Ant_Feed	Amplitude	Phase	Paired_With

Figure 6. An example version of the antenna codebook.

One thing to be noted is that the codebook is defined at the chipset, not at the antenna elements.

Averaging the Power Density for MPE (sPD):

Spatial averaging is needed to determine the MPE values from power density simulation results over the 4 cm² area required by the FCC.

5 Uncertainty Budget for Simulation

Below is a table summarizing the budget of the uncertainty contributions of the numerical algorithm and of the rendering of the simulation setup. The table was filled using the IEC 62704-1 ED1 [3].

Table 2 – Preliminary budget of the uncertainty contributions of the numerical algorithm for the validation- or testing-setup

Uncertainty component	Probability distribution	Divisor $f(d, h)^1$	C_i^2	Uncertainty %
Mesh resolution	Normal	1	1	1.2%
ABC	Normal	1	1	0.2%
Power budget	Normal	1	1	0.5%
Model Truncation				0.01%
Convergence	Rectangular	1,73	1	0.2%
DUT dielectrics	Normal	1	1	5.1%
Lossy conductors	Rectangular	1,73	1	2.4%
Combined standard uncertainty ($k = 1$)				9.6%

Note 1: The divisor is a function of the probability distribution and degrees of freedom (ν_i and ν_{eff}).

Note 2: c_i is the sensitivity coefficient that is applied to convert the variability of the uncertainty component into a variability of psPD.

6 Simulation vs. Measurement

To validate the accuracy of the model, measured MPE and simulated MPE values for n258 are summarized below in Table 3, with unit W/m². The difference between simulated and measured MPE values is in dB. Simulated and measured point PD for different beams for n258 are shown in Figure 7.

a) Side-Firing Array, n258

Beam ID	Ant Pol	Simulation (W/m ²)	Measurement (W/m ²)	Delta = Sim – Meas. (dB)
		S4	S4	S4
38	V	22.42	19.9	0.52

Appendix A: Worst Phase Derivation for Beam Pair

For beam pairs, since the relative phase between two beams is unknown, so finding the worst-case PD by sweeping the relative phase for all possible angles is required for conservative assessments.

Assuming E-field and H-field for beam ID a are $\{E_{x_a}, E_{y_a}, E_{z_a}\}$ and $\{H_{x_a}, H_{y_a}, H_{z_a}\}$, respectively; for beam pair which is ID b is $\{E_{x_b}, E_{y_b}, E_{z_b}\}$ and $\{H_{x_b}, H_{y_b}, H_{z_b}\}$, respectively. The relative phase between beam a and b is θ , the combined E and H field after beam pairing is:

$$\begin{aligned} E_{x_pair_i}(\theta) &= E_{x_a} + E_{x_b} \times e^{-j\omega\theta} \\ E_{y_pair_i}(\theta) &= E_{y_a} + E_{y_b} \times e^{-j\omega\theta} \\ E_{z_pair_i}(\theta) &= E_{z_a} + E_{z_b} \times e^{-j\omega\theta} \end{aligned}$$

$$\begin{aligned} H_{x_pair_i}(\theta) &= H_{x_a} + H_{x_b} \times e^{-j\omega\theta} \\ H_{y_pair_i}(\theta) &= H_{y_a} + H_{y_b} \times e^{-j\omega\theta} \\ H_{z_pair_i}(\theta) &= H_{z_a} + H_{z_b} \times e^{-j\omega\theta} \end{aligned}$$

The combined PD can be calculated as:

$$\begin{aligned} PD_{x_pair_i}(\theta) &= E_{y_pair_i}(\theta) \times H_{z_pair_i}(\theta)^* - E_{z_pair_i}(\theta) \times H_{y_pair_i}(\theta)^* \\ PD_{y_pair_i}(\theta) &= E_{z_pair_i}(\theta) \times H_{x_pair_i}(\theta)^* - E_{x_pair_i}(\theta) \times H_{z_pair_i}(\theta)^* \\ PD_{z_pair_i}(\theta) &= E_{x_pair_i}(\theta) \times H_{y_pair_i}(\theta)^* - E_{y_pair_i}(\theta) \times H_{x_pair_i}(\theta)^* \\ PD(\theta) &= \frac{1}{2}[(\text{Re}(PD_{x_pair_i}(\theta)))^2 + (\text{Re}(PD_{y_pair_i}(\theta)))^2 + (\text{Re}(PD_{z_pair_i}(\theta)))^2]^{1/2} \end{aligned}$$

Sweep θ from 0 degree to 360 degree to find the worst case beam pair.

Appendix B: 4 cm² Averaging PD and Scaling Factor

4 cm² Averaging PD: The following tables show the simulated sPD results for all three different arrays, at both band n258, n261 and band n260. Table a), b), and c) show the results for n258, for side array, back array 1, and back array 2, respectively; table d), e), and f) show the results for n261, for side array, back array 1, and back array 2, respectively; table g), h) and i) show the results for n260, for side array, back array 1, and back array 2, respectively.

a) Simulated sPD (W/m²) at 4 cm² averaging for side array at n258.

Scaling factor calculation: The following tables show the scaling factor results for all three different modules, at both band n258, n261 and band n260. The scaling factor is defined as the MPE internal design limit (5 W/m²) divided by the simulated averaged power density. Table a), b), and c) show the results for n258, for side, back, and front modules, respectively; table d), e), and f) show the results for n261, for side, back, and front modules, respectively; table g), h) and i) show the results for n260, for side, back, and front modules, respectively.

a) *Scaling factor for side array n258*

Appendix C: MPE (sPD) Simulation Using New Guideline from Qualcomm

This document provides the changes from what we have submitted from last year, following the new guidelines from Qualcomm, that 2nd generation of Smart Transmit (Smart-Tx GEN2) is used in this year's iPhone program.

The 1st generation of Smart Transmit (GEN1) assumes all transmit antennas are co-located and RF exposure is 100% overlapped, while the 2nd generation of Smart Transmit (GEN2) operates based on pre-defined antenna groups. In this revision, the antenna grouping is based on mmW module placement.

As an example of a wireless device having three mmW antenna (i.e., back-firing antenna 1 (BF1), back-firing antenna 2 (BF2) and side-firing (SF) antenna), Figure C.1 illustrates GEN1 and GEN2 operation.

Figure C.1. Smart transmit generate illustration, (a) GEN1, and (b) GEN2

The requirement and guidelines stated for GEN1 in all previous sections apply to GEN2. The additional requirement to characterize PD for GEN2 is described in this inclusion.

- All mmW modules need to be included in each simulation model
- 2D PD plots for different surfaces are not needed for Smart-Tx GEN2

C.1 Changes in Modeling Approach Using Smart-Tx GEN2

Simulation model needs to be large enough to include all the antenna modules located inside the EUT, so that the mutual coupling can be properly calculated. Unlike GEN1, simulation of a part of the EUT (right part of Figure C.2) will not work. Instead, the entire EUT must be simulated as illustrated in the left side example in Figure C.2 for GEN2.

Additionally, the simulation domain needs to be sufficiently large for “Qualcomm MG Script” to extract valid E- and H-fields from all adjacent exposure surfaces of the EUT extended by at least 35 mm in all directions. To accomplish this, if CST is used, recommended setting for the “radiation boundary” is at least 40 mm away from EUT to well contain all adjacent exposure surfaces (S1~S6 in Figure 2).

Figure C.2. Simulation model examples.

C.2 GEN2 PD Generation Using Qualcomm MG Script

Use “Qualcomm MG script” to extract E- and H-fields from the validated simulation and to assess the mutual coupling between all the mmW modules and all the beams in the codebook to determine the backoff value for each mmW module. Note the assessment and backoff value derivation are automated with “Qualcomm MG script”. Once the script is done with assessment, it will provide the *sim.power_{limit}* (backoff is already included) for all the beams for all three channels for the specified *sPD_{design_{target}}*.

C.3 Additional Verifications for GEN2

The sPD for GEN2 cannot be finalized until the additional verifications described in this section are performed and passed. The below steps are followed for verifications in the mid channel.

VERIFICATION 1: Use “Qualcomm MG script” to print the sPD plots for all the beams selected and evaluated for model validation. Compare the printed sPD plot to the corresponding

simulated/measured sPD, the printed sPD distributions should match the simulated sPD distributions as shown in Table C.1 and C.4 to verify that “Qualcomm MG script” is properly used.

VERIFICATION 2: “Qualcomm MG script” identifies the worst-case 4cm² sPD and its location (x,y,z). This worst-case 4cm² sPD is maximum 4cm² sPD value out of all exposure surfaces when assuming the worst beam from each of the antenna modules are active. The script will then identify the worst beam from each module that contributes the most to the worst 4cm² sPD and print their contribution factor, as well as the worst surface corresponding to the worst-case 4cm² sPD, backoff value for each antenna module and *verification.sim.powerlimit* (before backoff) value for each identified beams.

Use CST (or other EM simulation tool) to calculate the simulated contribution factor for the identified beams. The simulated contribution factor, $c_{simulated}(i,j)$, for beam i from QTM j can be computed by

$$c_{simulated}(i,j) = 4cm^2 \text{ PD at } (x, y, z) \text{ at } verification.sim.powerlimit / PD_design_target$$

Verify:

1. the printed contribution factor, $c(i,j)$, matches the simulated contribution factor, $c_{simulated}(i,j)$, obtained from CST (or other EM simulation tool) within 2% of numerical tolerance.
2. the normalized *combined sPD* does not exceed 1.0, i.e., *normalized combined sPD* = $\sum(b_j * c(i,j)) \leq 1.0$
where *combined sPD* = sPD from current antenna module + sPD contributions from other antenna modules; b_j = backoff value for antenna module j , j = antenna module #; $c(i,j)$ = contribution factor of beam i from antenna module j to the worst 4cm² sPD. Both b_j and $c(i,j)$ are printed from “Qualcomm MG script”.

VERIFICATION 3: Measure power density for the beams identified by “Qualcomm MG script” on their corresponding worst surfaces printed from the script. Set the device in FTM mode, the sPD measurement should be performed at the reference power level with CW modulation. Scale the measured sPD to obtain 4cm² sPD(i,j) for beam i from antenna module j at their *input.power.limit*. Demonstrate that the *combined sPD* (i.e., $\sum[c(i,j)*sPD(i,j)]$) is less than or equal to *sPD_design_target* within the uncertainty at reference power level, i.e., *combined sPD* = $\sum[c(i,j)*measured\ 4cm^2\ sPD(i,j)] \leq sPD_design_target + \text{uncertainty at reference power level}$.

As an example of one of the iPhone programs, which contains 2 antenna modules (i.e., Module0 (back-firing array 1 and back-firing array 2) and Module1 (side-firing array)), the following verifications are for n258, n261 and n260, respectively.

1) Band n258

“Qualcomm MG script” identifies beam 171 and 30 from Module0 and Module1, respectively. The script prints below information corresponding to the identified worst-case 4cm² sPD:

- the backoff values (in linear) for Module0 and Module1: $b_0 = 0.9550$; $b_1 = 0.9550$

- the worst location coordinates (x, y, z) in meter = $(0.03776, -0.00800, -0.00200)$
- the worst-surface = S4 (right surface, see Figure C.2)
- the $verification.sim.power_{limit}$ (before backoff) for the beams 171 and 30 is -0.90 dBm and 3.61 dBm, respectively.
- worst surface for Module0 is S4 (Back); worst surface for Module1 is S4 (Right)
- the contribution factors $c(171, 0) = 0.0314$ and $c(30, 1) = 0.9981$ at the worst-case $4cm^2$ sPD location $(0.03776, -0.00800, -0.00200)$

As shown in Table C.2, the printed contribution factor matches the simulated contribution factor within 2%, and the *normalized combined sPD* is less than 1.0. Thus, the verification 2 is completed for this program.

As shown in Table C.3, the *combined* measured sPD at the worst location $\leq sPD_design_target$ uncertainty at reference power level. Thus, the verification 3 is completed for this program.

Table C.1 - Simulated sPD distributions for selected beams.

Beam ID	Surface	Simulated sPD	Printed out from Qualcomm MG Script
171	S2		
	S3		

Table C.2 - Contribution factors from Qualcomm MG script and from CST for selected beams, and normalized *combined sPD* verification, for device with 2 antenna modules.

Worse-case surface					S4 (right surface)	
Worst-case location (x,y,z) in meters					(0.03776, -0.00800, -0.00200)	
<i>sPD_design_target</i> (W/m ²)					5	
Value printed by MG Script					Value by EM tool	
Module #	Beam ID	$c(i,j)$, $i=\text{beam ID}$, $j=\text{module \#}$	Backoff factor b_j	$\text{verification.sim.power}^{\text{limit}}$ (before backoffs) [dBm]	Simulated 4cm ² sPD at (0.03776, -0.00800, -0.00200) with $\text{verification.sim.power}^{\text{limit}}$ on S4 (W/m ²)	$c_{\text{simulated}}(i,j)$
0	171	0.0314	0.9550	-0.90	0.1560	$0.1560/5 = 0.0312$
1	30	0.9981	0.9550	3.61	4.9750	$4.9750/5 = 0.9950$
Verify 1	$uujc(i,j)=c_{\text{simulated}}(i,j), i = 171, 30; j = 0, 1$					
Verify 2	$b_0 \times c(171,0) + b_1 \times c(30,1) = 0.9550 \times 0.0314 + 0.9550 \times 0.9981 = 0.9832 \leq 1$					

Table C.3: Measured 4cm² sPD on worst surface and *combined sPD* at worst-case location for device with 2 antenna modules.

Module#	Beam ID	Dominant Surface	Measured 4cm ² sPD at input.power.limit on dominant surface (W/m ²)
0	171	S2 (Back)	4.666
1	30	S4 (Right)	4.907
<i>combined sPD</i> at the worst-case location (x,y,z)			$c(171,0) \times \text{meas.4cm}^2\text{sPD}(171,0) + c(30,1) \times \text{meas.4cm}^2\text{sPD}(30,1) = 0.0314 \times 4.666 + 0.9981 \times 4.907 = 5.0442 \text{ W/m}^2$

sPD_design_target + uncertainty at reference power level of 1 dB	$= 5 * 10^{(+1/10)} = 6.3 \text{ W/m}^2$
Verify	combined sPD < sPD_design_target + uncertainty at reference power level

Note $c(i,j)$ is obtained from Table C.2.

2) Band n261

“Qualcomm MG script” identifies beam 161 and 22 from Module0 and Module1, respectively. The script prints below information corresponding to the identified worst-case 4cm² sPD:

- the backoff values (in linear) for Module0 and Module1: $b_0 = 0.9772$; $b_1 = 0.9550$
- the worst location coordinates (x, y, z) in meter = (0.03776, -0.01400, -0.00200)
- the worst-surface = S4 (right surface, see Figure C.2)
- the *verification.sim.power_{limit}* (before backoff) for the beams 161 and 22 is -1.00 dBm and 3.44 dBm, respectively.
- worst surface for Module0 is S2 (back); worst surface for Module1 is S4 (right)
- the contribution factors $c(161, 0) = 0.0327$ and $c(22, 1) = 1.0000$ at the worst-case 4cm² sPD location (0.03776, -0.01400, -0.00200)

As shown in Table C.5, the printed contribution factor matches the simulated contribution factor within 2%, and the *normalized combined sPD* is less than 1.0. Thus, the verification 2 is completed for this program.

As shown in Table C.6, the *combined* measured sPD at the worst location $\leq sPD_design_target$ uncertainty at reference power level. Thus, the verification 3 is completed for this program.

Table C.4 - Simulated sPD distributions for selected beams.

Beam ID	Surface	Simulated sPD	Printed out from Qualcomm MG Script
161	S2		
	S3		
22	S1		

Table C.5 - Contribution factors from Qualcomm MG script and from CST for selected beams, and normalized *combined sPD* verification, for device with 2 antenna modules.

Worse-case surface					S4 (right surface)	
Worst-case location (x,y,z) in meters					(0.03776, -0.01400, -0.00200)	
sPD_design_target (W/m ²)					5	
Value printed by MG Script					Value by EM tool	
Module #	Beam ID	$c(i,j)$, i =beam ID, j =module #	Backoff factor b_j	$verification.sim.power_{limit}$ (before backoffs) [dBm]	Simulated 4cm ² sPD at (0.03776, -0.01400, -0.00200) with $verification.sim.power_{limit}$ on S4 (W/m ²)	$c_{simulated}(i,j)$

0	161	0.0327	0.9772	-1.00	0.1650	$0.1650/5 = 0.0330$
1	22	1.0000	0.9550	3.44	5.0500	$5.0500/5 = 1.0100$
Verify 1	$uujc(i,j)=c_{simulated}(i,j), i = 161, 22; j = 0, 1$					
Verify 2	$b_0 \times c(161,0) + b_1 \times c(22,1) = 0.9772 \times 0.0327 + 0.9550 \times 1.0000 = 0.9870 \leq 1$					

Table C.6: Measured 4cm² sPD on worst surface and *combined sPD* at worst-case location for device with 2 antenna modules.

Module#	Beam ID	Dominant Surface	Measured 4cm ² sPD at input.power.limit on dominant surface (W/m ²)
0	161	S2 (Back)	5.402
1	22	S4 (Right)	4.731
<i>combined sPD</i> at the worst-case location (x,y,z)			$c(161,0) \times \text{meas.4cm}^2\text{sPD}(161,0) + c(22,1) \times \text{meas.4cm}^2\text{sPD}(22,1) = 0.0327 \times 5.402 + 1.0000 \times 4.731 = 4.908 \text{ W/m}^2$
<i>sPD_design_target</i> + uncertainty at reference power level of 1 dB			$= 5 \times 10^{(+1/10)} = 6.3 \text{ W/m}^2$
Verify			combined sPD < <i>sPD_design_target</i> + uncertainty at reference power level

Note $c(i,j)$ is obtained from Table C.5.

3) Band n260

“Qualcomm MG script” identifies beam 10 and 38 from Module0 and Module1, respectively. The script prints below information corresponding to the identified worst-case 4cm² sPD:

- the backoff values (in linear) for Module0 and Module1: $b_0 = 0.9772$; $b_1 = 0.9772$
- the worst location coordinates (x, y, z) in meter = (-0.00400, 0.04000, -0.00593)
- the worst-surface = S4 (right surface, see Figure C.2)
- the *verification.sim.power_limit* (before backoff) for the beams 10 and 38 is 6.23 dBm and 2.71 dBm, respectively.
- worst surface for Module0 is S2 (back); worst surface for Module1 is S4 (right)

- the contribution factors $c(10, 0) = 1.0000$ and $c(38, 1) = 0.0136$ at the worst-case 4cm^2 sPD location $(-0.00400, 0.04000, -0.00593)$

As shown in Table C.8, the printed contribution factor matches the simulated contribution factor within 2%, and the *normalized combined sPD* is less than 1.0. Thus, the verification 2 is completed for this program.

As shown in Table C.9, the *combined measured sPD* at the worst location $\leq$ *sPD design target* uncertainty at reference power level. Thus, the verification 3 is completed for this program.

Table C.7 - Simulated sPD distributions for selected beams.

Beam ID	Surface	Simulated sPD	Printed out from Qualcomm MG Script
10	S2		
	S3		

38	S1		Beam 38 38.5GHz Front: $4\text{cm}^2\text{-avg. PD}$ 
	S2		Beam 38 38.5GHz Back: $4\text{cm}^2\text{-avg. PD}$ 
	S4		Beam 38 38.5GHz Right: $4\text{cm}^2\text{-avg. PD}$ 

Table C.8 - Contribution factors from Qualcomm MG script and from CST for selected beams, and normalized *combined sPD* verification, for device with 2 antenna modules.

Worse-case surface					S4 (right surface)	
Worst-case location (x,y,z) in meters					(-0.00400, 0.04000, -0.00593)	
<i>sPD_design_target</i> (W/m ²)					5	
Value printed by MG Script					Value by EM tool	
Module #	Beam ID	$c(i,j)$, $i=\text{beam ID}$, $j=\text{module \#}$	Backoff factor b_j	$\text{verification.sim.power}^{\text{limit}}$ (before backoffs) [dBm]	Simulated 4cm ² sPD at (-0.00400, 0.04000, -0.00593) with $\text{verification.sim.power}^{\text{limit}}$ on S4 (W/m ²)	$c_{\text{simulated}}(i,j)$
0	10	1.0000	0.9772	6.23	4.9010	$4.9010/5 = 0.9802$
1	38	0.0136	0.9772	2.71	0.0630	$0.0630/5 = 0.0126$
Verify 1	$c(i,j)=c_{\text{simulated}}(i,j), i = 10, 38; j = 0, 1$					
Verify 2	$b_0 \times c(10,0) + b_1 \times c(38,1) = 0.9772 \times 1.0000 + 0.9772 \times 0.0136 = 0.9905 \leq 1$					

Table C.9 - Measured 4cm² sPD on worst surface and *combined sPD* at worst-case location for device with 2 antenna modules.

Module#	Beam ID	Dominant Surface	Measured 4cm ² sPD at input.power.limit on dominant surface (W/m ²)
0	10	S2 (Back)	4.615
1	38	S4 (Right)	4.996
<i>combined sPD</i> at the worst-case location (x,y,z)			$c(10,0) \times \text{meas.4cm}^2 \text{ sPD}(10,0) + c(38,1) \times \text{meas.4cm}^2 \text{ sPD}(38,1) = 1.0000 \times 4.615 + 0.0136 \times 4.996 = 4.6829 \text{ W/m}^2$

sPD_design_target + uncertainty at reference power level of 1 dB	$= 5 \cdot 10^{(+1/10)} = 6.3 \text{ W/m}^2$
Verify	combined sPD < sPD_design_target + uncertainty at reference power level

Note $c(i,j)$ is obtained from Table C.8.
