15.247g,h FHSS Characteristics

Frequency Hop Timing

The timing is handled in the high level state machine. Every time through the high level state machine, the Realtime Clock is read. The time read from the Realtime Clock is compared to see if the tenths of seconds is not equal to the previous tenths of seconds value. If not equal, it hops to the next hop channel. The average hop rate is 100 ms. This high level state machine does not override tag encoders/decoders, so depending on a tag in the field, it will vary a bit from hop to hop, but no more than 15% on a single given hop.

Select of Hop Frequency

The Encompass 4H operates in the 902 to 928 MHz industrial, scientific, and medical radio band. The channel frequencies are defined by an algorithm below. There is no ability to synchronize this hopping with other devices. Therefore the Encompass 4H does not have the ability to be coordinated with other systems. Each frequency is used equally on average by the transmitter.

Frequency Hop Sequence

There are 101 unique frequency steps from 902.5 to 927.5 MHz with a step size of 250kHz, Channel 0=902.5 MHz, Channel 1=902.75 MHz, Channel 2=903 MHz, ...Channel 100=927.5 MHz. The reader has a Real Time Clock (RTC) that is continually running independently of the frequency setting, and is read many independent times in between the reader setting the transceiver to a new frequency. The RTC has a hundredth of a second field that will be a number between 00 and 99. The reader software will add 1 to the currently read value of this hundredth value resulting in a random number between 1 and 100. It will then add this value to the current RF frequency channel. If the resulting channel is valid, it will jump the RF frequency to that channel. If the resulting channel is out of range, it will roll around to the first channel and add the remainder of the number of channels that it was out of range. This will result in a 50/50 chance of the new frequency ending up being a forward hop or a backwards hop. Statistically, over the short term, the frequency hopping is completely random and the resultant end value of a given RF frequency is further randomized as the algorithm is influenced by every single random step that occurred since the reader was powered up. Over the long term, every channel will statistically be occupied the same amount of time as every other channel.

Additional Information

All frequency hopping modes were evaluated, there was no significant difference in timing or hopping sequencing between frequency hopping modes. FHSS mode represented in the plotted data was taken with FHSS mode SeGo.

15.247 Number of Hopping Frequencies

The EUT must have its hopping function enabled. Use the following spectrum analyzer settings:

Span = the frequency band of operation

RBW $\geq$ 1% of the span

VBW $\geq$ RBW

Sweep = auto

Detector function = peak

Trace = max hold

Allow the trace to stabilize. It may prove necessary to break the span up to sections, in order to clearly show all of the hopping frequencies. The limit is specified in one of the subparagraphs of this Section. Submit this plot(s).

EUT performed within the requirements of the applicable standard ☒ Yes ☐ No <i>Les Payne</i>			

15.247 Time of Occupancy (Dwell Time)

The EUT must have its hopping function enabled. Use the following spectrum analyzer settings:

Span = zero span, centered on a hopping channel

RBW = 1 MHz

VBW $\geq$ RBW

Sweep = as necessary to capture the entire dwell time per hopping channel

Detector function = peak

Trace = max hold

Trigger = video (positive trace)

If possible, use the marker-delta function to determine the dwell time. If this value varies with different modes of operation (e.g., data rate, modulation format, etc.), repeat this test for each variation. The limit is specified in one of the subparagraphs of this Section. Submit this plot(s). An oscilloscope may be used instead of a spectrum analyzer.

15.247 Carrier Frequency Separation

The EUT must have its hopping function enabled. Use the following spectrum analyzer settings:

Span = wide enough to capture the peaks of two adjacent channels

Resolution (or IF) Bandwidth (RBW) $\geq$ 1% of the span

Video (or Average) Bandwidth (VBW) $\geq$ RBW

Sweep = auto

Detector function = peak

Trace = max hold

Allow the trace to stabilize. Use the marker-delta function to determine the separation between the peaks of the adjacent channels. The limit is specified in one of the subparagraphs of this Section. Submit this plot.

Test Procedure: ANSI C63.10-2013

15.247 (d) Spurious RF Conducted Emissions

Use the following spectrum analyzer settings:

Span = wide enough to capture the peak level of the in-band emission and all spurious emissions (e.g., harmonics) from the lowest frequency generated in the EUT up through the 10th harmonic. Typically, several plots are required to cover this entire span.

RBW = 100 kHz

VBW ≥ RBW

Sweep = auto

Detector function = peak

Trace = max hold

Allow the trace to stabilize. Set the marker on the peak of any spurious emission recorded. The level displayed must comply with the limit specified in this Section. Submit these plots.

Model Number:		MPRXFH					
Description:		Multiprotocol Reader Extreme- Frequency Hopper				Clause 15.247(d)	
Ambient Temperature			Relative Humidity		Barometric Pressure		
24 °C			32 %		101.30 kPa		
EUT performed within the requirements of the applicable standard ☒ Yes ☐ No <i>J Payne</i>							
Port	Channel	Modulation	Peak Output Power (dBm)		Reading (dBm)	-20dBc (dBm)	Pass/Fail
0	Low	ego	28.44		28.77	8.77	Pass
1	Low	ego	28.90		29.01	9.01	Pass
2	Low	ego	28.94		28.90	8.9	Pass
3	Low	ego	28.90		29.12	9.12	Pass
