1.4 Application details

Date of receipt of application : 2007-06-22
Date of receipt of test item : 2007-06-25
Date of test : 2007-07-03 to 2007-07-13

1.5 Test item (EUT)

Description of test item	:	76 GHz millimeter-wave radar sensor
Type identification	:	ARS 3-A
S/N	:	ARS 3-A B4-160
Manufacturer	:	A.D.C. Automotive Distance Control Systems GmbH Kemptenerstr. 99 88131 Lindau Germany

1.6 Technical data

TX frequency range	:	76.000 – 77.000 GHz
TX frequency range EUT	:	76.375 GHz – 76.598 GHz
Channel	:	1
Modulation	:	FMCW (chirp)
EIRP (measured)	:	91.2 mW (19.6 dBm) Peak / Peak = Average
Peak Power Density	:	0.081 μ W/cm ² (Peak) @ 3m
not-in-motion-mode	:	0.2nW/cm ² @ 3m
Antenna	:	integrated antennas (mechanical scanning)
Designation of emission	:	223MF0N
Transmission time per cycle	:	66 ms
Intermission time per cycle	:	0 ms
Duty factor	:	100 %
Extreme power supply U DC	:	10.8 – 15.6 V
Nominal power supply U DC	:	13.2 V

1.6.1 Operation conditions

The sample was set in operating and in “not-in-motion”-mode via CAN-bus and a notebook with special software to simulate a moving or standing car.

2 Technical test

2.1 Summary of test results

- No deviations from the technical specification (s) were ascertained in the course of the performed tests.
- The deviations as specified in 2.5 were ascertained in the course of the performed tests.

This test report :

- describes the first test
- describes an additional test
- is a verification of documents
- is only valid with the test report no.

2.2 Test environment

The environmental conditions are documented especially for each test.

2.3 Measurement and test set-up

The measurement and test set-up is defined in the technical specification FCC part 15 Section 15.253 and IC RSS 210.

2.4 Test equipment utilized and test set-up

2.4.1 Test set-up for the measurement in the frequency range 12 GHz to 40 GHz

Spurious radiation (EIRP; PEP)

Frequency f (GHz)	Measurement distance (m)	a(sys) [dB]	a(f) [dB] at lowest freq.	a(k) [dB]	g [dBi]
12.4 ... 18.0	0.5	34.8	51.6	1.7	18.4
18.0 ... 27.0	0.5	38.2	54.4	2.2	18.4
27.0 ... 40.0	0.5	36.6	55.1	2.8	21.3

Calculation of system attenuation = free space attenuation + cable loss - antenna gain

$$a(\text{sys}) = a(f) + a(k) - g$$

2.5 Test results

2.5.1 Test results overview

This test was performed :

in addition to the test report no.

Verification of EUT :

EUT is in accordance with the technical description

EUT is not in accordance with the technical description

The equipment is compliant to FCC requirement

2.5.2 Remarks on methods of measurements

The Radar head is positioned in a non-conductive fixture and can be rotated and tilted in all angles.

The radiated measurements are performed in vertical and horizontal plane in the frequency range from 9 kHz to 231 GHz in a semi-anechoic chamber, a fully-anechoic chamber and in our lab. The EUT is positioned on a non-conductive support with a height of 0.80 m above a conductive ground plane that covers the whole chamber. The receiving antennas are conform with specifications ANSI C63.2-1996 clause 15 and ANSI C63.4-2003 clause 4.1.5. These antennas can be moved over the height range between 1.0 m and 4.0 m in order to search for maximum field strength emitted from EUT. The measurement distances between EUT and receiving antennas are indicated in the test set-ups for the various frequency ranges. For each measurement, the EUT is rotated in all three axes until the maximum field strength is received.

The wanted and unwanted emissions are received by spectrum analysers where the detector modes and resolution bandwidths (RBW) over various frequency ranges are set according to requirement ANSI C63-4-2003 clause 4.2.

1. Measurements of the EIRP and power density (PD) at fundamental frequency

The measurements are carried out according to FCC guideline "Millimetre Wave Test Procedure" with a spectrum analyser (SA), harmonic mixer with appropriate frequency range and a rectangular standard gain horn antenna (SGH) with matching wave guide dimensions. The conversion loss of the external mixer is taken into account in the SA power level reading automatically.

The radiated power measurements are performed with resolution bandwidth filter (RBW) of 1.0 MHz and a video filter of 1 MHz. This filter setting is sufficiently broad enough to receive the peak envelope power (PEP) of the EUT.

The distance for fundamental power measurement generally is 3.0 m. The SA level scale shows the dimension dBm. With a SGH and a measured antenna aperture area the power density can be calculated from the equation:

$$\begin{aligned} \text{Power density} &= \frac{\text{EIRP}}{\text{Antenna aperture area}} \quad [\text{mW/cm}^2] \\ \text{pd} &= \frac{\text{eirp}}{a} - \quad [\text{dB}(\text{mW/cm}^2)] \end{aligned}$$

2. Measurements of frequency stability

In order to measure the frequency stability of the EUT under normal and extreme test conditions, it is necessary to use a smaller RBW filter (here 100 kHz or 300 kHz) so that the spectral lines of the modulated signal are displayed correctly in frequency domain. This setting allows to read the occupied bandwidth and the peak frequency deviation value directly.

Frequency measurements are performed under normal test conditions (normal power supply voltage and normal temperature).

Then the test is repeated with extreme test conditions. For extreme test conditions the EUT is placed in a climatic chamber where the front door is made of stable polystyrene. The EUT can radiate through the front door without any additional path losses. The climatic chamber together with the EUT is cooled down to -20 °C for 1 hour. Then frequency and power density measurements are carried out with power supply set to minimum and maximum values.

The climatic chamber together with the EUT is warmed up at a rate of + 1°C/minute. During warming-up time the frequency stability and the EIRP is monitored constantly. After 2 hours the temperature stability at 55 °C is reached. Then frequency and power density measurements are carried out with minimum and maximum power supply.

3. Measurements of field strength and power density at spurious frequencies

Spurious frequencies are produced by transmitter and receiver when the EUT is active (vehicle is moving). When the EUT is in Not-in-motion-mode, the emissions of the TX has to be reduced more than 25 dB. According to FCC requirements 15.209 and 15.253, spurious emissions have to be investigated as maximum field strength values in the frequency range from 9 kHz to 40 GHz, and as maximum power density in the frequency range > 40 GHz up to 231 GHz. Where possible, the measurement distance shall be 3 m.

In the low frequency range (9 kHz to 30 MHz), the receiving antenna is an active loop antenna which is positioned at 3 m distance in a shielded, anechoic chamber (see page 8). In case of required measuring distances > 3 m, a distance correction factor is used to calculate the received field strength.

Spurious field strength measurements in the frequency range 30 MHz to 12 GHz are carried out in a shielded semi-anechoic test chamber. The measurement distance is 3 m.

In the frequency range 12 GHz to 40 GHz, spurious field strength measurements are performed in a shielded fully anechoic chamber with rectangular SGH's. The measurement distances are indicated underneath each plot, and a calculation for field strength is added, where all relevant factors like cable losses, antenna factors, etc are taken into account.

In the frequency range 40 GHz to 231 GHz, spurious frequencies are measured as power densities. For further remarks see section 1.). The RBW and VBW are set to such a value that spurious power levels are clearly readable above the fundamental noise level of spectrum analyzer.

4. Measurements of maximum safe level for radiated power density

According to FCC § 1.1307, 1.1310, 2.1091, and 2.1093 and also according to ETSI/EN 301 091 measurements are carried out in order to evaluate the impact of human exposure to RF radiation. For this test the EUT is in normal operation mode.

The measurements are applicable only for far field conditions. The near field area extends to a distance of R (meters) and can be calculated from the following equation:

$$R < 2 * L^2 / \lambda$$

with R = distance in meters, L = largest dimension of either receiving or transmitting horn antenna (L = 0.02 m), and λ = wavelength in meters. In case of 76 GHz (λ = 0.0039 m), the far field starts at $R > 0.205$ m.

The peak power density is measured in 3 m distance as 0,082 μ W/cm².

Peak Power (EIRP)	$EIRP = PD * 4\pi * R^2$
	EIRP = 91.2 mW (19.6 dBm) Peak
	Peak = Average (FMCW chirp)

As the sample works with FMCW-modulation there is no difference between peak and average value of the output power.

5. RF Exposure

Limit of maximum ERP for frequencies above 1.5 GHz is 3 W. See FCC § 2.1091 (EIRP = 91.2 mW)

RF Exposure for mobile conditions at **R = 0.2 m** distance from EUT

PD	= EIRP / (4 π * R ²)
PD	= 0.018 mW/cm ²

Limit of maximum permissible exposure (MPE) for uncontrolled environment: 1.0 mW/cm². See FCC § 1.1310.

2.5.4 Not-In-motion Mode

Section 15.253 (b) (1)

To show compliance with the requirements of Part 15.253 (b) (1) – Not-In-Motion mode, we tested with a can-bus interface on a laptop with special software to simulate moving or not-moving of the car.

Description of the test:

We placed the antenna 20 cm in front of the radar equipment with vertical polarisation to obtain max. power.
We started the simulation on the PC.

Here we switched the simulation to TX/RX Off mode (not in motion simulation).

The maximum power density in not-in-motion-mode is 0.2 nW/cm² (see next plot).

CETECOM ICT Services GmbH

Test report No.: 2-4679/07-01-02-A

Date : 2007-07-13

Page 24 of 48

Plot: not-in-motion-mode

Date: 11.JUL.2007 09:29:19

Measurement distance d = 0.20 m

Calculation of system attenuation = free space attenuation - antenna gain

$$\begin{aligned} a(\text{sys}) &= 55.7 \text{ dB} - 20.5 \text{ dB} \\ &= 35.2 \text{ dB} \end{aligned}$$

The $a(\text{sys})$ is calculated in the Analyser reading.

Output power = $257 \mu\text{W}$ (-5.9 dBm)

Calculation :

$$\begin{aligned} \text{Power density} &= \text{EIRP (mW)} / 4 * \pi * 300\text{cm} * 300\text{cm} \\ &= 257 \mu\text{W} (-5.9 \text{ dBm}) / 1130973.4 \text{ cm}^2 \end{aligned}$$

Peak Power density = 0.2 nW/cm^2

LIMITS:

SECTION 15.253 (B) (1)

Frequency range [GHz]	Measurement distance [m]	Not-in-motion [dBm/cm ²] [nW/cm ²]	
76.0 – 77.0	3.0	-37	200

Verdict : pass

3 Plots, graphs and data sheets

Plot no.: 1

Measurement distance d = 0.5 m

Calculation of system attenuation = free space attenuation - antenna gain

$$\begin{aligned} a(\text{sys}) &= 64.2 \text{ dB} - 23.0 \text{ dB} \\ &= 41.2 \text{ dB} \end{aligned}$$

Calculation :

$$\text{Output power} = -21.6 \text{ dBm} + 41.2 \text{ dB} = 19.6 \text{ dBm} = 91.2 \text{ mW}$$

$$\begin{aligned} \text{Power density} &= \text{EIRP (mW)} / 4\pi \cdot 300\text{cm} \cdot 300\text{cm} \\ &= 91.2 \text{ mW (19.6 dBm)} / 1130973.4 \text{ cm}^2 \end{aligned}$$

$$\text{Peak Power density} = 0.081 \mu\text{W/cm}^2$$

$$\text{Limit} = 60 \mu\text{W/cm}^2 \text{ at 3.0 m}$$

Verdict :	pass
