Denmark

Contact Person: B. sc. Tom Ringtved

Summary of test result

The device fulfils the requirements of FCC part 15, 247(g), processing gain.

Responsible for Accreditation Scope: _____ Responsible for Test Report: _____

Introduction

This report describes the results of the processing gain measurement for the Digianswer Bluetooth™ Headset DGABTHS100 using the FCC CW jamming margin method.

Requirement

Hybrid systems that employ a combination of both direct sequence and frequency hopping modulation techniques shall achieve a processing gain of at least 17 dB from the combined techniques.

Modification of measurement method

Despreading is accomplished by correlating the received bit stream with the bit pattern of the access code. Then with the value of the correlator output will be decided if the access code is valid or not.

That means if the access code is not valid a “bit error” occurs for the Bluetooth device.

For this reason the CW jamming margin method uses the ratio between the valid and invalid access codes (IACR) instead of the ratio between BER and invalid access codes.

Another reason to use this criteria is the fact, that the Bluetooth technology uses the access code to find the correct sampling point. That means if the access code cannot be found, all other bits in the transmission cannot be sampled successfully.

System loss

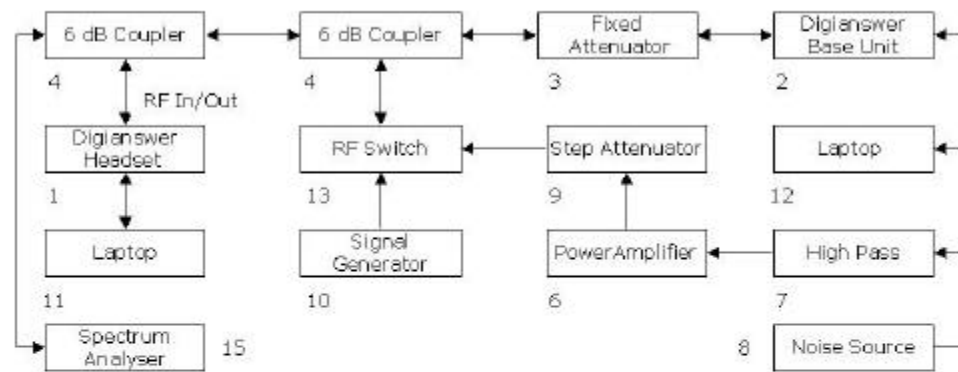

In the formula for calculation of the processing gain the term system losses appears. In Bluetooth there are two major reasons to use this system loss:

1. The non optimal sampling time. The CW jamming method assumes that the optimal sampling time as determined before, in fact, as described above, it will be determined via the access code.
2. Total loss due to attenuation in the RF part.

This two points produce a system loss which will be much greater than 2 dB. The exact value will be calculated because a maximum of 2 dB will be accepted by FCC.

Measurement Set-up

To measure the IACR the following test set-up was used:

Measurement set-up

Note: For detailed information for the equipment please see test equipment list

To setup the connection and to measure the IACR a special debug program is used. It is installed on the laptop and communicates with the Headset via the RS 232 serial port.

In the result the number of invalid access codes of a packet for 255 transmissions is given. For this test 200 packets (51000 bursts) are measured. The selected IACR of 0.1%, means that 51 access codes are not valid.

The level of the wanted signal is set to -40 dBm for all single measurements.

Measurement Results

S/N Measurement

The measurement for S/N was performed by adding noise to the wanted signal. The noise level was adjusted until the IACR reached 0.1%.

Due to the fact that a measured noise level depends essentially on the characteristic of the measurement filter. If you measure at the RF input of the EUT, the relevant filter will be the analyser filter, which has a gaussian characteristic. This characteristic is completely different from the internal IF filter. For this reason the signal/noise ratio was measured behind the IF filter (worst case).

With this measurement configuration the S/N ratio was 16.4 dB

Jammer/Signal Measurement (JSR)

The jammer signal was stepped in 50 kHz steps over the receiving channel. For every step the jammer level was adjusted until the IACR was 0.1 %. The ratio between wanted signal power and the jammer power at the RF input of the device is the required Jammer to Signal ratio.

With this measurement configuration the JSR has the following results:

Jammer Offset/kHz	Jammer/Signal (dB)
-500	-54,5
-450	-54,4
-400	-54,2
-350	-54,6
-300	-54,1
-250	-52,9
-200	-51,7
-150	-50,6
-100	-50,3
-50	-49,4
0	-49,1
50	-51,8
100	-49,9
150	-52,1
200	-51,4
250	-52,6
300	-52
350	-53,6
400	-54
450	-54,3
500	-56,7

Disregarding the data in the red marked data fields (-500; -450, -350, +500 kHz) the worst data point is at 450 kHz with a value of -54,3 dB.

Processing gain calculation

With these values we calculated the processing gain:

$M_j = JSR$

$G_p = S/N + M_j + L_{sys} = 16.4 - 12.9 + 2.0 = 5.5 \text{ dB}$

The processing gain for the DSS is 5.5 dB.

The processing gain for FHSS part is calculated as:

$10 * \log 32 = 15 \text{ dB}$ (32 hopping channels in hybrid mode)

This means for the total processing gain of the hybrid system:

$15 \text{ dB} + 5.5 \text{ dB} = 20.5 \text{ dB}$

This is above the minimum value of 17 dB stated in FCC rules.

The device passes the requirement of this clause.
