

Question:

The modular approval request letter states that above 3.6V, the unit would refuse to transmit. Pg 25 of the report shows RF output power measurements at 3.8V. Please clarify.

Response:

The unit provided for testing did not have the production version of software. The software monitoring of the voltage regulation was not present in the test code used. The production units have a high voltage shutdown level set at 3.6V. Please note that the 3.8V measurement on page 25 of the test report was at the +15% variation limit.
