

Operation principle:

The function is to control the focal length of camera, especially in zoom lens (zoom in and zoom out), in order to control the lens exactly; when the user release the switch, the data transmit will be stop immediately.

Input data of four bits to the encoder of the transmitter, then convey to the receiver for the signal carrier of 433.92 with frequency. After the receiver accepts the code, decode the signal into the amplifier, enlarges the signal to relay to action.

There are security codes for avoiding the possibility of duplicating codes in adjacent systems. The coding must be matching with the companion receiver.

The transmitter emission after the user release the switch:
