

Description of circuit

Power support

The transmitter is fed by 12V DC or car power supply

Antenna:

The transmitter utilize dipole antenna. The power of this signal (Power manager) will be send to MCU .Audio signal will be process by audio input ,then it will be send to FM stereo modulate. MCU will output pulse to trigger the oscillator and the encoder to genetate a carrier frequency and digital code signal when frequency and momeory adjustment was pressed .Then the serially digital signal of encoder will mixed with the carrier at modulator stage by was of FSK mode (frequency Modulation) from the RF VCO,this process uitalize PLL which compare 19KHZ frequency Modulation signal with signal which is from trigger the oscillator Then this signal will pass through time frequency to change into the frequency that required .This signal then pass through LC frequency select network and will be sent to transmitter antenna for transmitting.
